#### **Problem**

To check whether volume spike is a good predictor of daily closing price

# **Preparations**

- 1. Raw data
  - a. 2 years data of IDX30 stocks from 2022-07-01 09:00:00+07:00 to 2024-04-05 09:00:00+07:00
  - b. Data granularity is hourly
  - c. Sample raw data on ACE HARDWARE

timestamp	open_aces	close_aces	volume_aces
2024-06-28 12:00:00+07:00	860	855	826700
2024-06-28 13:00:00+07:00	860	855	826700
2024-06-28 14:00:00+07:00	860	855	826700
2024-06-28 15:00:00+07:00	855	855	3038000
2024-06-28 16:00:00+07:00	855	855	0

# 2. Data Processing

- a. Calculated daily percent change and hours to market close
- b. Split data to train and test for further testing
- c. Define target rules, eg if daily percent change is greater than 0.1%
- d. Normalize every feature using interquartile scaler (robust scaler) except temporal data
- e. Calculate rolling standard deviation of every predictors. In this case, the calculation is rolling every 25 days \* 7 hours
- f. Define the volume spike, eg if spike is greater than the 1 \* rolling volume standard deviation

g.

# **Check Statistical Significance**

We use Pearson's correlation to quantify the link between volume traded and *daily* (not hourly) close prices. Student's T-Test to check whether the spike population is sufficiently different with the non-spike population

### The hypothesis is as follows

*Null Hypothesis (H0)*: There is no significant difference in the daily percentage change between instances with and without volume spikes.

Alternative Hypothesis (H1): There is a significant difference in the daily percentage change between instances with and without volume spikes.

Below is the result, sorted by T-test significance

It appears that volume spike is a weak predictor for daily closing prices, as even the strongest correlation, exemplified by ACES, only reaches a correlation coefficient of 0.29. Moreover, the significance between populations with spikes versus no spikes varies greatly across different assets. For instance, in AMRT, these populations are distinctly different, whereas in ARTO, the distribution appears entirely random.

Notably, ACES, despite its relatively higher correlation with daily prices, shows an unusually low t-test metric. This suggests that there is no discernible statistical difference in prices between populations with volume spikes versus no spikes. Conversely, AMRT exhibits a very high t-test metric but a low correlation coefficient. This discrepancy may imply that while there is a correlation between volume spikes and closing prices, either the dataset is insufficiently large or the observed differences are not significant enough to establish statistical significance."

This version maintains clarity while highlighting the specific observations about correlation coefficients, t-test metrics, and the variability across different assets in relation to volume spikes and daily closing prices

# Modeling

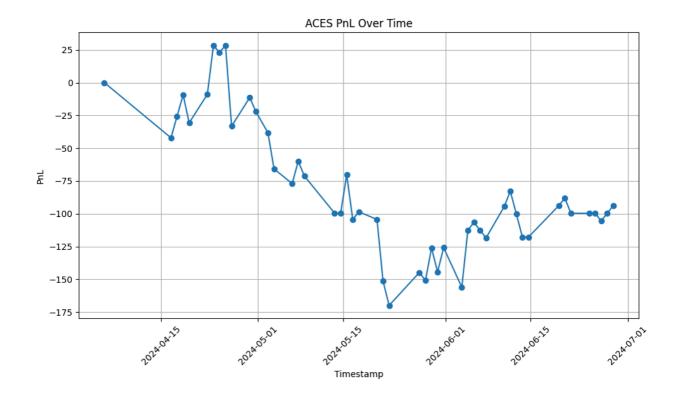

Nevertheless, we attempt to employ an LSTM deep learning model to predict closing prices. We input sequences consisting of 25 days \* 7 hours of previous closing data and the latest volume as predictors, aiming to demonstrate the relationship between volume and price. The model utilizes these predictors to forecast whether the daily percent price change exceeds 0.1%.

Initially, our focus is on the extreme cases of ACES, which exhibits the highest volume-price correlation, and AMRT, with the highest T-test value.

	Predicted Negative ACES	Predicted Positive ACES
Actual Negative ACES	72.56	3.13
Actual Positive ACES	17.12	7.19

For ACES, the model demonstrates reasonable ability to predict percent changes. Out of every 100 predictions, it correctly forecasts that the price will not exceed the 0.1% limit approximately 72 times. It also accurately predicts instances where the price exceeds this threshold about 7 times. However, in approximately 17 instances, the model predicts the price will stay below the threshold, but it actually exceeds it, resulting in missed trading opportunities. Conversely, around 3 times, the model predicts the price will rise when it does not, potentially leading to trading losses.

Now we try to bring the model to life using dataset that it has not seen yet, opening up position when it predicted up, and close by the end of day

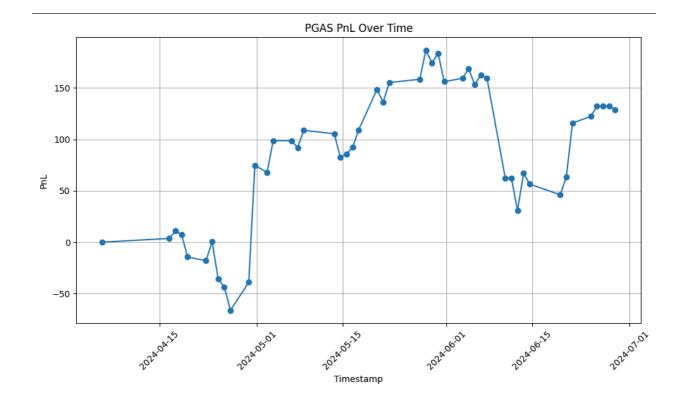

Over the 3-month period, a majority of trades have yielded positive results. This, coupled with a favorable confusion matrix, suggests that using price and volume as predictors could be a promising approach. However, it's notable that when the model predictions are incorrect, the resulting drawdowns are quite substantial. Therefore, there is a clear need to minimize errors in the model.

#### On the other hand, the best performing asset is PGAS

	Predicted Negative PGAS	Predicted Positive PGAS
Actual Negative PGAS	82.81	0.63
Actual Positive PGAS	11.67	4.90

For PGAS, the model demonstrates reasonable ability to predict percent changes. Out of every 100 predictions, it correctly forecasts that the price will not exceed the 0.1% limit approximately 83 times. It also accurately predicts instances where the price exceeds this threshold about 6 times. However, in approximately 11 instances, the model predicts the price will stay below the threshold, but it actually exceeds it, resulting in missed trading opportunities. Conversely, around 0.63 times, the model predicts the price will rise when it does not, potentially leading to trading losses.

While the model performs well on PGAS, it shows a notably low T-test score of 0.547042 and a modest correlation of 0.117721. This raises concerns that the LSTM model may primarily emphasize the predictive power of previous closing prices rather than volumes, challenging our assumption of a volume-price correlation.

#### Conclusion

In summary, our analysis suggests that there is insufficient evidence to reject the hypothesis that there is no relationship between volume and volume spikes with most of the asset's closing prices, as indicated by both statistical tests and predictive modeling.

However, several notable flaws in our experiments highlight areas for improvement. The primary limitation is the lack of data, both in terms of asset selection and time frame. To address this, we could expand our dataset by including more historical data prior to 2022. It's important to note that extending the dataset to include the Covid-19 period may introduce biases due to unique market conditions at that time, which is why we initially avoided its inclusion.

Additionally, another significant flaw is the uniform application of parameters, statistics, and models across all assets. Moving forward, it's essential to analyze each asset independently, considering that their behaviors may vary significantly.
